are known to affect the mating behavior of fishes in many species (Deaton, 2008; Marimuthu et al., 2001; Arockiaraj et al., 2004). Egg guarding is the most common form of parental care (Clutton-Brock, 1991), and in majority of species only one parent is involved in parental care. Among teleost families male care is much more

Overview. Mating systems and parental care vary tremendously from species to species. Every species differs in how it protects its young from predators and provides its young with food, if it does so at all. The physical environment as well as behavioral dynamics in intraspecies relationships all influence parental care.

In biology, paternal care is parental investment provided by a male to his own offspring. It is a complex social behaviour in vertebrates associated with animal mating systems, life history traits, and ecology. Paternal care may be provided in concert with the mother or, more rarely, by the male alone. The provision of care,

Many species of fishes do not care for their eggs and fingerlings. They leave the spawning grounds after fertilization. For such species of fishes the lacking parental care behaviour is compensated by the production of large number of eggs. Such fishes lay over 300 million eggs at a time.

Parental Care may refer to any behaviour that contributes to offspring survival.

Forms of care may include the preparing of a physical rearing environment, the provisioning of offspring or the defending of offspring from predators. Species such as ectothermic vertebrates may produce self-sufficient young, and thus no parental
