In this function, three variables are needed: (1) a variable to hold the value of the cumulative sum, (2) an index variable for the loop, and (3) a temporary copy of the input array c. In the function they look like this: functionrun_Luhn(c : incdeint) returninteger is. i : integer; sum : integer; tmp : codeint;

Luhn algorithm executes the following steps on this array of digits. Lets say the credit card number is a 1 a 2 a 3 ... a 16 (a 1 being a digit in the number) 1. Reverse the number. a 16 a 15 ... a 3 a 2 a 1. 2. Add the digits at the odd positions: Sum even = a 16 + a 14 + a 12 + ... + a 2. 3.

Luhn algorithm. Last Updated: 25-09-2020. The Luhn algorithm, also known as the modulus 10 or mod 10 algorithm, is a simple checksum formula used to validate a variety of identification numbers, such as credit card numbers, IMEI numbers, Canadian Social Insurance Numbers. The LUHN formula was created in the late 1960s by a group of mathematicians. Shortly thereafter, credit card companies adopted it.

Luhn mod N algorithm is a modified form of Luhn mod 10 algorithm. Just as the name implies, in mod N algorithm we can have N number of valid characters, as in mod 10 algorithm we had 10 valid characters (ie, digits 0-9).

the cs50.h that I have does not have a function: get_long_long(), so, for me, the code does not compile.My compiler suggested: getlonglong() which credit card company is, normally, contained in the left digits of the card number, not in the right digits. so the posted code logic is (probably) not correct.
